### **Application**

Frese PV can be installed in domestic and commercial heating and cooling systems.

The valve is a dynamic, adjustable differential pressure control valve (DPCV) that ensures the differential pressure across the load or circuit is constant.

The valve ensures good modulating control and reduces the risk of noise from thermostatic radiator valves and 2-port control valves.

Frese PV can be installed in conjunction with Frese S (adjustable flow limiter) to provide 100% control of the flow and differential pressure regardless of pressure fluctuations in the system. See PVS Technote.

#### Benefits

- The valve offers three in-built functions: adjustable differential pressure control, isolation and P/T plugs for pressure verification
- Frese PV eliminates noise problems caused by over pressure
- Differential pressure can be set and adjusted on site
- Tamper-proof presetting device on top of the valve, meaning there is no need for the valve sealing after presetting
- Presetting is simple using the graphs shown on pages
   9-13

#### **Features**

- Maximum differential pressure: 400 kPa
- Removable  $\Delta P$  cartridge allows forward as well as backflushing
- Size range: DN15 to DN50
- Maximum flow: 15m<sup>3</sup>/h
- Built-in P/T plugs for ΔP verification

### Setting the valve

The valve is easily set by means of a 4mm hexagonal key. The flow rate of the valve can be determined from the flow rate graphs for the valve dimension in question.

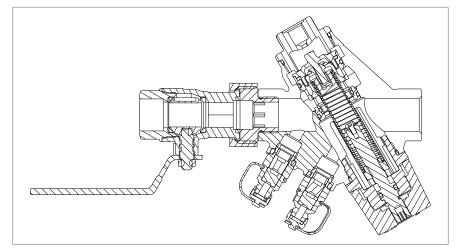

See the flow rate graphs of the valve on pages 9 and 13 for further information about the Pre-setting.

To set the valve to the desired downstream differential pressure, the valve should be set at the minimum position and then adjusted in accordance with the presetting graphs.

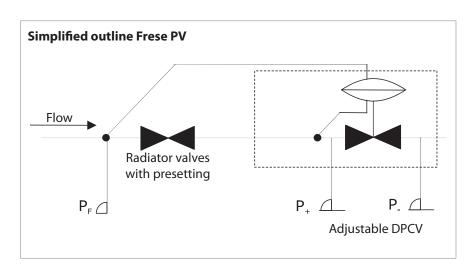

#### Design

Frese PV consists of a differential pressure regulation unit, isolating ball valve, P/T-plugs and partner valve which is installed in the flow.

Frese PV system fem./fem. with union and isolation ball valve

#### Technical data

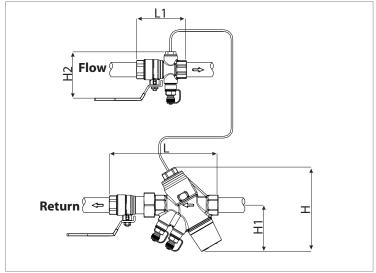

**Housing:** DZR, Brass PPS 40% glass

Flow setting: PPO

**Spring:** Stainless steel

Diaghragm:HNBRO-rings:EPDMPressure class:PN16Max. differential pressure:400 kPa

**Temperature range:**  $-10^{\circ}\text{C to} + 120^{\circ}\text{C}$  **Capillary tube:**  $\emptyset$ 3, L = 1000mm

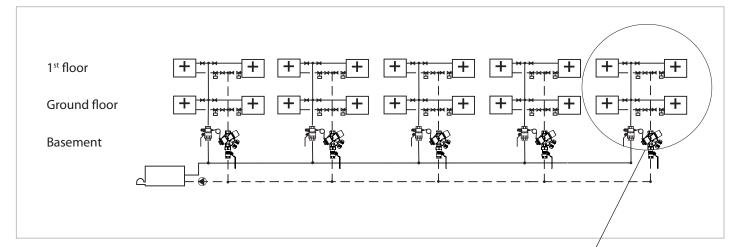

**Frese PV System** - Valve combination, capillary tube, isolation ball valve at the supply- and return line.

#### Example

Outline of the heating system in one of the sections. 5 staircases with 4 flats each. Pump and tank farther away than indicated in the example.

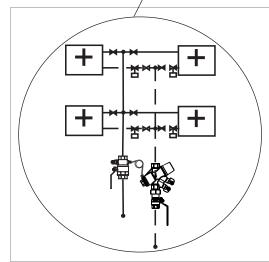

Evidently the pressure will be higher in the supply pipes near the pump than e.g. in the critical pipe.

In this case the purpose of Frese PV is to maintain pressure of approx. 12 kPa across the supply and the return line.

Specifying the characteristics of the building, the calorific requirement was rated at 125 l/h per flat.

Motor valves were chosen for the control of the flow. The Kvs-value of these should be as close to 0.36 m<sup>3</sup>/h as possible. (125 l/h and 12 kPa),  $Q = Kv * \sqrt{\Delta p}$ .

As already mentioned a differential pressure of 12 kPa should be maintained at a flow of  $4 \times 125 = 500 \text{ l/h}$ . From the scheme on page 3, which shows the technical data of Frese PV, a Frese PV DN15 will be suitable for the purpose.

Index Circuit

#### Example

The adjustment setting of the Frese PV+ valve is specified on the basis of the graph. In order to make reading easier the graphs indicating the pressure in the circuit are arranged at intervals of 5 kPa. Still, the graphs can be offset according to the specified pressure of 12 kPa in our circuit.

In the given example we want to maintain 12 kPa in the circuit at a flow rate of 500 l/h. From the intersection of the 12 kPa graph and the horizontal line indicating 500 l/h a line perpendicular to the x-axis is made to read the pre-set value. Now you will see that the valve is to be pre-set by app. 7 turns on the scale.

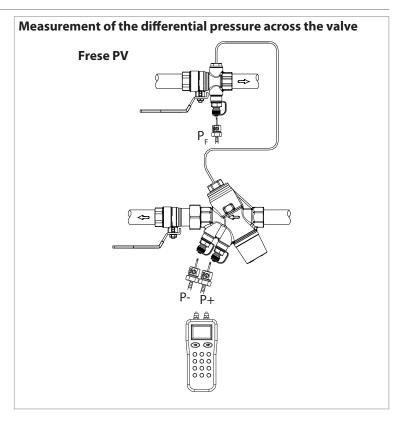

The minimum pressure drop required will be 1.9 kPa across the valve.

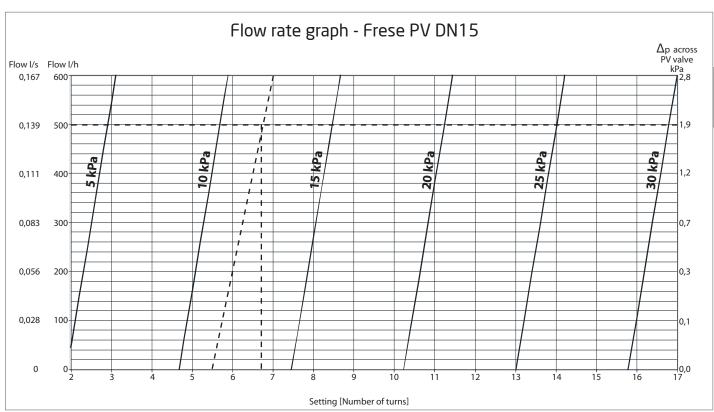

Consequently, the total pressure drop required when rating the pump will be:

$$\Delta P_{p} = \Delta P_{s} + \Delta P_{v} = 12 + 1.9 = 13.9 \text{ kPa}.$$

Now the pump can be throttled to operate at its opti-

mum, by measuring from P  $_{\rm F}$  to P- ( $\Delta P_{\rm pump}$  ). To verify that the calculated secondary pressure drop across the circuit is correct, measurements can be carried out from P<sub>c</sub> to P+, and should read 12 kPa as dimensioned.

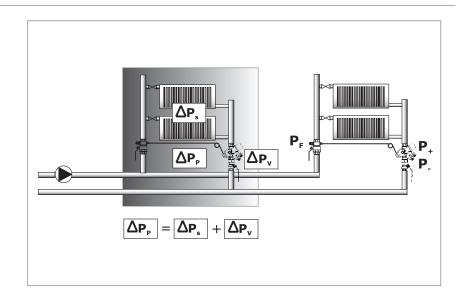

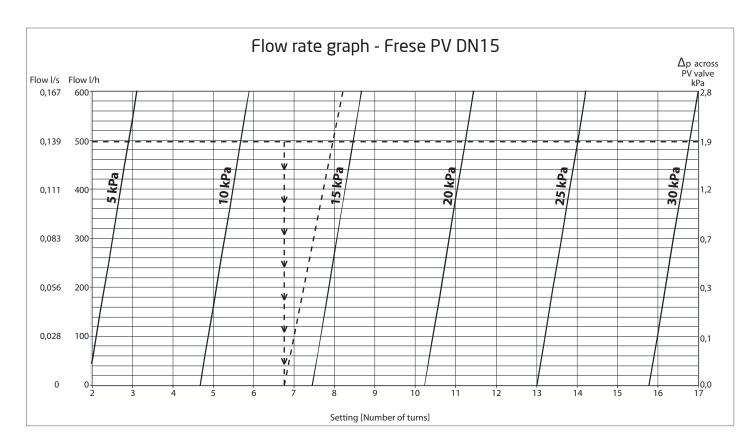

### Example

#### Please note:

As the flow is reduced in the circuit in question the pressure increases in reverse ratio to the flow, which is due to the P-band of the adjustment spring. The valve still compensates for this. However, the pressure will nowhere in the circuit be as high as the pump pressure that would have been available if Frese PV had not been installed.

In this example the pressure increases to approx. 14 kPa as the graph is offset parallel to the course of flow. Furthermore, you can always read from the graph what the pressure in the circuit will be like at any flow rate below the rated 500 l/h.

### Text for technical specifications

The valve should be a dynamic difference control valve with the option of setting the differential pressure on site without suspension of operation.

The valve should limit the differential pressure in a circuit.

The valve should include optional P/T plugs for the verification of differential pressure in circuit and across the valve.

The valve scale should only be adjustable by means of a key.

The valve should be permanently marked with an indicator for flow direction.

Pressure rating PN16.
